Shalaw FA, Shakor JK, Hamedon TR, Jalal DMF, Qadir DO. Prevalence of Needle Stick and Sharp Injuries Among Surgical Specialist Hospital-Cardiac Center in Erbil City: A Cross-Sectional Study. Tabari Biomed Stu Res J. 2020;2(2):38-47.

#### **ABSTRACT**

**Introduction:** Needle-stick and sharp injuries (NSSI) pose a serious problem and a major risk of work-related transmitted diseases among healthcare workers. The extent of NSI in the Kurdistan region / Iraq hospitals has been unknown. The factors related to NSIs among healthcare workers were evaluated in the present study. The main purpose of this study is to determine the prevalence of NSSI and its associated factors among the respondents.

**Material and Methods:** The cross-sectional study was conducted on 150 randomly selected healthcare staff with a working experience of at least 1 year in the hospital. The study location is a surgical specialist hospital-cardiac center, situated in Erbil/Iraq. The self-administered questionnaire was used to collect information on socio-demographic, employment and individual characteristics, as well as data on NSSI, suffered in the past 12 months.

**Results:** The majority of participants (34%) were in the 30 to 35 year age group. Most were male (60.7%), married (61.3%), have at least degree qualification (89%). The prevalence of NSSI was 67%. Needle stick was the main frequent of NSSRs (66%). Needle recap was all the time done among health workers 104 (69%), they almost use both hands for recap 136 (91%). Education, working environment satisfaction, sleeping quality of the health staff have been considered the main indicators of NSSI.

Conclusion: The rate of NSSI was considered high in this study compared to the rates in many developing countries. Arrangement schedules for work and sleeping of staff could decrease the NSSI rate.

## Introduction

Needle-stick and sharp injuries (NSSI) pose a serious problem and a major risk of workrelated transmitted diseases among healthcare workers (HCW) in developing and developed countries (1). Each year,

about 3.5 million globally and around 600,000–1,000,000 workers in the United States suffered from NSSI (2,3). For healthcare worker, NSSIs is defined as any transcutaneous injury, a penetrating attempt

wound from a sharp object or needle that possibly will consequence in contact to blood or else other body fluids. Intravenous cannulation, unsuitable needle disposal, needle recapping, and set of drips are the most common accomplishments causing NSSIs according to many studies (4,5). The magnitude of NSSI risks and associated practices among HCWs was not well understood, particularly developing in countries (6). Several studies have stated that although the prevalence of blood borne pathogens in many developing countries is unusual, many exposures to NSSI in these countries remain undocumented (6,7), for instance, only 4% of the global prevalence of work-related HIV infection is reported in sub Saharan Africa, where about 70% of the world's HIV-infected people lives (7). In different researches for NSSI occurrences, various risk factors have been proposed like inappropriate routine of using protective kit, working in intensive care or in surgical units, inadequate work experience, and low information level of blood-borne infections (1,8). Research studies have been conducted on work-related NSSI contacts, but it is not yet clear why HCWs do not report sharp injury incidents (9,10). It is commonly accepted that the socio-demographic, occupational and individual factors are contributory factors to get NSSIs. Accident at work affects the well-being of people in the workplace, and therefore need to be prevented from occurring (8). It seems that the most important points for no reporting are factors such as heavy work, fear of job loss, and lack of knowledge about the importance of NSIs. Further studies are needed to determine the cause of this behavior. NSSI prevention are an essential factor of workplace prevention programs, and HCW's instruction on safety procedures needs to be a continuing activity at a hospital. The factors related to NSSIs among HCW were evaluated in the present study.

## **Methods**

## **Study Design and Study Population**

The cross-sectional study design was used to determine the proportion of NSSI and its associated factors. This study was conducted on 150 randomly selected HCW, including nurses, doctors, laboratory staff and nursing assistants with a working experience of at least one year in the hospital. The study location is a surgical specialist hospitalcardiac center, situated Erbil / Iraq. Medical employees consist of doctors, nurses, laboratory staffs and nursing assistances are approved may work full time part time and given rights to supply health care to patients in a special hospital or different health care facility.

#### **Materials**

The self-administered questionnaire, which was written in both English and Kurdish language was used to collect information. The questionnaire is divided into various sections. Section A collect information on socio-demographic background, such as gender, age, race, marital states and educational level. Section B is for the job position, length of employment, and working hours. Individual factors are collected in Section C, which collects information on the sleep pattern, overtime work and fatigue The last section, Section contained details of the occurrence of NSSIs suffered in the past 12 months, as well as the reasons for reporting or not reporting these injuries.

## **Data collection**

The questionnaire was distributed directly to the respondents. They were informed about the purpose of the study and those participating in did so on a voluntary basis. Besides, the respondents were made sure that their answers will be kept confidential and will only be used for research purposes. After the respondents have finished answering the questions, the questionnaires were collected immediately.

#### **Data Analysis**

The data was analyzed using the IBM Statistical Package of Social Sciences

(SPSS) version 21. Initially, the data was analyzed descriptively using frequency, and percentage. Inferential analysis (Chi-square test) was used to determine the association between **NSSIs** and the independent variables (socio-demographic, occupational, factors). individual Finally, and multivariate analysis using multiple logistic regressions was performed to determine the factors associated with the occurrence of NSSIs. The results were considered statistically significant if P < 0.05.

#### **Ethical Consideration**

This study had received ethical clearance from the Ethics Committee for Research Involving Human Subjects of surgical specialist hospital-cardiac center dated 22nd April 2017 and permission to do the study was given by the authority of the study location.

## Results

Most of the health staff in the area were male 91 (61%), and age were between 30-35 years, 51(34%), and married 92 (61%). Most of the participant have a diploma degree 133 (88.6%) (*Table 1*). For the occupational characteristics, out of 150 respondents, 62% of them are permanent staff, work as nurses,

74% of them had been in service for less than 5 years (57%) and most of them work in shifts (74.7%). Majority of the respondents (83.3%) working 40 hours, did not do overtime work (68.7%) and did not have part-time work (58.3%) (*Table 2*).

Data on the individual characteristics shows that out of 150 respondents, majority (57%) of them sleep less than 6 hours a night, 52% did not feel sleepy during working time and 48% did not feel tired at work. Majority of the respondents (47.3%) have a normal BMI (*Table 3*). 67% (101) of the respondents reported having sustained from NSSIs (*Figure 1*).

The more frequent cause of injury among respondents is syringe needle 80 (53.3%), and nearly 31 (30%) of workers were injured more than three times in the last one year (*Table 4*).

Pearson's chi-square test was used to determine the association among sociodemographic characteristics, employment characteristics, and individual factors with NSSI. *Table 5* below illustrates the result of the analysis. Overall, 101 (67%) of workers suffered from NSSI during the last years of during their experience working in hospital. There is statistically significant association among educational level, sleeping hours per night, getting enough sleep at night, quality

model, those who feel that they have good night sleep (OR=20.53, P=0.003), and good quality sleep were more likely to not suffer from NSSI (OR=7.26, P=0.023). And those who are more satisfied with working environment were more likely to not suffer from NSSI (OR=5.381, P= 0.010). Having other job and overtime work have come out with negative outcome.

## **Discussion**

The aim of this study was to find out the NSSI proposition among health worker. Most of health worker in this study were male (60.7%), married (61%) and have a diploma degree (89%). This study found that the prevalence of NSSI among respondents

are (67%) and nearly 30% of them had NSSI three times in last years. Needle stick were the main causes of the NSSI (66%). This is mainly due to most of the staff have overtime work (71%), and nearly half of the health worker unsatisfied with the work environment, certain independent variables are significantly associated with NSSI. Another reason may relate to needle recap which is done by (67%), and most of them use both hand for recap (91%). Some other studies also revealed that recapping needles as the main cause of NSSI (11,12). Stressful work environment and needle recapping have been identified as the reasons for NSSI (13,14). Similarly regarding to working environment this study found that NSSI was significantly associated unsatisfied with job

 $(X^2=6.8, P=0.033)$ . Among the sociodemographic characteristics, education level was significantly associated with NSSI  $(X^2=10.88, P=0.004)$ . Some other study indicates being female and have Nursing Bachelor's Degree significantly associated with (15).

The prevalence of NSSI (69%) in this study was higher compared to findings in many Ethiopian studies 43%, 26%, 19.1%, 37.1%,

58.8%, 18.7%, (5,11,14,16,17) respectively, study in China 27.5% (18), and study among dentist student in Brazil 43.1%, (19). In some Iranian studies the prevalence of NSI were 42.5%, 41.2% respectively and sharp injury was 19.2% (20, 21). The prevalence of NSSI in Serbian student was 29% (22). Sleep quality is identified as important factor for NSSI. More than half of the respondents in this study (57%) have night sleep of more

than 6 hours, and 52% of them do not feel sleepy during working time. While, nearly one quarter (24%) feel that they had poor night sleep qualities, and this is considerably better than sleep qualities in nursing staff in Turkey (79.1%) (23,24). Nurses with poor night sleep qualities were more prone to NSSI (24). Similar finding was observed in this study where high NSSI was found among respondents who did not have enough night sleep ( $X^2=13.263$ , Y=0.010), or those who did not have good sleep at night ( $X^2=11.35$ , Y=0.003), as well as those who sleep less than 6 hours at night ( $X^2=4.004$ , Y=0.045).

The results of logistic regression analysis showed that sleep quality is predictor for NSSI. These findings are more parallel with other study (25,26). Those who feel that they have adequate night sleep (OR=20.53,

P=0.003), and good quality sleep are more likely to not suffer from NSSI (OR=7.26, P=0.023). And those who are more satisfied with working environment were more likely to not suffer from NSSI (OR=5.381, P=0.010). The extend work to night shift and satisfaction have always determined as predictors of NSSI (27).

#### Conclusion

The NSSI prevalence in this study (67%) is higher compared to the figures found in other developing countries. Level of education, working environment satisfaction, sleep quality of the health staff have been found to be main factors associated with NSSI. Improvement of work schedule and sleep quality could decrease the NSSI rate.

Table 6. Logistic Regression predicting likelihood of having NSSI
